General Description

The MAX6641 temperature sensor and fan controller accurately measures the temperature of its own die and the temperature of a remote pn junction. The device reports temperature values in digital form using a 2-wire serial interface. The remote pn junction is typically the emitter-base junction of a common-collector pnp on a CPU, FPGA, or ASIC.

The 2-wire serial interface accepts standard System Management Bus (SMBus)TM write byte, read byte, send byte, and receive byte commands to read the temperature data and program the alarm thresholds. The temperature data controls a PWM output signal to adjust the speed of a cooling fan, thereby minimizing noise when the system is running cool, but providing maximum cooling when power dissipation increases. The device also features an over-temperature alarm output to generate interrupts, throttle signals, or shut down signals. The MAX6641 operates from supply voltages in the 3.0V to 5.5V range and typically consumes 500µA of supply current.

The MAX6641 is available in a slim 10-pin µMAX[®] package and is available over the automotive temperature range (-40 \degree C to +125 \degree C).

Applications

Desktop Computers Notebook Computers **Workstations** Servers Networking Equipment Industrial

Features

- ♦ **Tiny 3mm x 5mm µMAX Package**
- ♦ **Thermal Diode Input**
- ♦ **Local Temperature Sensor**
- ♦ **Open-Drain PWM Output for Fan Drive**
- ♦ **Programmable Fan Control Characteristics**
- ♦ **Automatic Fan Spin-Up Ensures Fan Start**
- ♦ **±1°C Remote Temperature Accuracy (+60°C to +145°C)**
- ♦ **Controlled Rate of Change Ensures Unobtrusive Fan-Speed Adjustments**
- ♦ **Temperature Monitoring Begins at Power-On for Fail-Safe System Protection**
- ♦ OT **Output for Throttling or Shutdown**

Pin Description

Detailed Description

The MAX6641 temperature sensor and fan controller accurately measures the temperature of its own die and the temperature of a remote pn junction. The device reports temperature values in digital form using a 2 wire serial interface. The remote pn junction is typically the emitter-base junction of a common-collector pnp on a CPU, FPGA, or ASIC. The MAX6641 operates from supply voltages of 3.0V to 5.5V and consumes 500µA of supply current. The temperature data controls a PWM output signal to adjust the speed of a cooling fan. The device also features an over-temperature alarm output to generate interrupts, throttle signals, or shut down signals.

SMBus Digital Interface

From a software perspective, the MAX6641 appears as a set of byte-wide registers that contain temperature data, alarm threshold values, and control bits. A standard SMBus-compatible 2-wire serial interface is used to read temperature data and write control bits and alarm threshold data. These devices respond to the same SMBus slave address for access to all functions.

The MAX6641 employs four standard SMBus protocols: write byte, read byte, send byte, and receive byte (Figures 1, 2, and 3). The shorter receive byte protocol allows quicker transfers, provided that the correct data register was previously selected by a read byte instruction. Use caution when using the shorter protocols in multimaster systems, as a second master could overwrite the command byte without informing the first master. The MAX6641 has four different slave addresses available; therefore, a maximum of four MAX6641 devices can share the same bus.

Temperature data within the 0°C to +255°C range can be read from the read external temperature register (00h). Temperature data within the 0°C to +125°C range can be read from the read internal temperature register (01h). The temperature data format for these registers is 8 bits, with the LSB representing +1°C (Table 1) and the MSB representing +128°C. The MSB is transmitted first. All values below 0°C are clipped to 00h.

Table 1 details the register address and function, whether they can be read or written to, and the power-on reset (POR) state. See Tables 1–5 for all other register functions and the *Register Descriptions* section. Figure 4 is the MAX6641 block diagram.

Register Descriptions

Temperature Registers (00h, 01h)

These registers contain the 8-bit results of the temperature measurements. Register 00h contains the temperature reading of the remote diode. Register 01h contains the ambient temperature reading. The value of the MSB is +128°C and the value of the LSB is +1°C. The MSB is transmitted first. The POR state of the temperature registers is 00h.

Configuration Byte Register (02h)

The configuration byte register controls the timeout conditions and various PWMOUT signals. The POR state of the configuration byte register is 00h. See Table 2 for configuration byte definitions.

Remote and Local OT *Limits (03h, 04h)*

Set the remote (03h) and local (04h) temperature thresholds with these two registers. Once the temperature is above the threshold, the OT output is asserted low (for the temperature channels that are not masked). The POR state of the remote \overline{OT} limit register is 6Eh and the POR state of the LOCAL OT limit register is 50h.

OT *Status (05h)*

Read the OT status register to determine which channel recorded an over-temperature condition. Bit D7 is high if the fault reading occurred from the remote diode. Bit D6 is high if the fault reading occurred in the local diode. The OT status register is cleared only by reading its contents. Reading the contents of the register also makes the OT output high impedance. If the fault is still present on the next temperature measurement cycle, the corresponding bits and the \overline{OT} output are set again. After reading the \overline{OT} status register, a temperature register read must be done to correctly clear the appropriate status bit. The POR state of the \overline{OT} status register is 00h.

MAXM

MAX6641

MAX664

SMBus-Compatible Temperature Monitor with Automatic PWM Fan-Speed Controller

Table 2. Configuration Byte Definition (02h)

OT *Mask (06h)*

Set bit D7 to 1 in the OT mask register to prevent the OT output from asserting on faults in the remote-diode temperature channel. Set bit D6 to 1 to prevent the OT output from asserting on faults in the local-diode temperature channel. The POR state of the \overline{OT} mask register is 00h.

Fan-Start Duty Cycle (07h)

The fan-start duty-cycle register determines the PWM duty cycle where the fan starts spinning. Bit D3 in the configuration byte register (MIN DUTY CYCLE) determines the starting duty cycle. If the MIN DUTY CYCLE bit is 1, the duty cycle is the value written to the fanstart duty-cycle register at all temperatures below the fan-start temperature. If the MIN DUTY CYCLE bit is zero, the duty cycle is zero below the fan-start temperature and has this value when the fan-start temperature is reached. A value of 240 represents 100% duty cycle. Writing any value greater than 240 causes the fan speed to be set to 100%. The POR state of the fan-start duty-cycle register is 60h, 40%.

Fan Maximum Duty Cycle (08h)

The fan maximum duty-cycle register sets the maximum allowable PWMOUT duty cycle between 2/240 (0.83% duty cycle) and 240/240 (100% duty cycle). Any values greater than 240 are recognized as 100% maximum duty cycle. The POR state of the fan maximum duty-cycle register is F0h, 100%. In manual control mode, this register is ignored.

Fan-Target Duty Cycle (09h)

In automatic fan-control mode, this register contains the present value of the target PWM duty cycle, as determined by the measured temperature and the dutycycle step size. The actual duty cycle needs a settling time before it equals the target duty cycle if the dutycycle rate of change register is set to a value other than zero. The actual duty cycle needs the time to settle as defined by the value of the duty-cycle rate-of-change register; therefore, the target duty cycle and the actual duty cycle are often different. In manual fan-control mode, write the desired value of the PWM duty cycle directly into this register. The POR state of the fan-target duty-cycle register is 00h.

10 __

Fan Instantaneous Duty Cycle (0Ah)

Read the fan instantaneous duty-cycle register to determine the duty cycle at PWMOUT at any time. The POR state of the fan instantaneous duty-cycle register is 00h.

Remote- and Local-Diode Fan-Start Temperature (0Bh, 0Ch)

These registers contain the temperature threshold values at which fan control begins in automatic mode. See the *Automatic PWM Duty-Cycle Control* section for details on setting the fan-start thresholds. The POR state of the remote- and local-diode fan-start temperature registers is 00h.

Fan Configuration (0Dh)

The fan-configuration register controls the hysteresis level, temperature step size, and whether the remote or local diode controls the PWMOUT signal; see Table 1. Set bit D7 of the fan-configuration register to zero to set the hysteresis value to 5°C. Set bit D7 to 1 to set the hysteresis value to 10°C. Set bit D6 to zero to set the fan-control temperature step size to 1°C. Set bit D6 to 1 to set the fan-control temperature step size to 2°C. Set bit D5 to 1 to control the fan with the remote-diode's temperature reading. Set bit D4 to 1 to control the fan with the local-diode's temperature reading. If both bits D5 and D4 are high, the device uses the highest PWM value. If both bits D5 and D4 are zero, the MAX6641 runs in manual fan-control mode where only the value written to the fan-target duty-cycle register (09h) controls the PWMOUT duty cycle. In manual fan-control mode, the value written to the fan-target duty-cycle register is not limited by the value in the maximum dutycycle register. It is, however, clipped to 240 if a value above 240 is written. The POR state of the fan-configuration register is 00h.

Duty-Cycle Rate of Change (0Eh)

Bits D7, D6, and D5 of the duty-cycle rate-of-change register set the time between increments of the duty cycle. Each increment is 2/240 of the duty cycle; see Table 3. This allows the time from 33% to 100% duty cycle to be adjusted from 5s to 320s. The rate-ofchange control is always active in manual mode. To make instant changes, set bits D7, D6, $D5 = 000$. The POR state of the duty-cycle rate-of-change register is A0h (1s time between increments).

Duty-Cycle Step Size (0Fh)

Bits D7–D4 of the duty-cycle step-size register change the size of the duty-cycle change for each temperature step. The POR state of the duty-cycle step-size register is 50h; see Table 4.

Table 3. Duty-Cycle Rate-of-Change Register (0Eh)

Table 4. Duty-Cycle Step-Size Register (0Fh)

PWM Frequency Select (10h)

Set bits D7, D6, and D5 (select A, select B, and select C) in the PWM frequency-select register to control the PWMOUT frequency; see Table 5. The POR state of the PWM frequency select register is 40h, 33Hz. The lower frequencies are usually used when driving the fan's power-supply pin as in the *Typical Application Circuit*, with 33Hz being the most common choice. The 35kHz

MAX6641 MAX6641

Table 5. PWM Frequency Select (10h)

frequency setting is used for controlling fans that have logic-level PWM input pins for speed control. Dutycycle resolution is decreased from 2/240 to 4/240 at the 35kHz frequency setting.

PWM Output The PWMOUT signal is normally used in one of three ways to control the fan's speed:

- 1) PWMOUT drives the gate of a MOSFET or the base of a bipolar transistor in series with the fan's power supply. The *Typical Application Circuit* shows the PWMOUT pin driving an n-channel MOSFET. In this case, the PWM invert bit (D4 in register 02h) is set to 1. Figure 5 shows PWMOUT driving a p-channel MOSFET and the PWM invert bit must be set to zero.
- 2) PWMOUT is converted (using an external circuit) into a DC voltage that is proportional to duty cycle. This duty-cycle-controlled voltage becomes the power supply for the fan. This approach is less efficient than 1), but can result in quieter fan operation. Figure 6 shows an example of a circuit that converts the PWM signal to a DC voltage. Because this circuit produces a full-scale output voltage when PWMOUT = 0V, bit D4 in register 02h should be set to zero.
- 3) PWMOUT directly drives the logic-level PWM speed-control input on a fan that has this type of input. This approach requires fewer external components and combines the efficiency of 1) with the low noise of 2). An example of PWMOUT driving a fan with a speed-control input is shown in Figure 7. Bit D4 in register 02h should be set to 1 when this configuration is used.

Whenever the fan has to start turning from a motionless state, PWMOUT is forced high for 2s. After this spin-up period, the PWMOUT duty cycle settles to the predetermined value. If spin-up is disabled (bit 2 in the configuration byte $= 1$), the duty cycle changes immediately from zero to the nominal value, ignoring the duty-cycle rate-of-change setting.

Figure 5. Driving a P-Channel MOSFET for Top-Side PWM Fan Drive

Figure 6. Driving a Fan with a PWM-to-DC Circuit

Figure 7. Controlling a PWM Input Fan with the MAX6641's PWM Output (Typically, the 35kHz PWM Frequency is Used)

The frequency-select register controls the frequency of the PWM signal. When the PWM signal modulates the power supply of the fan, a low PWM frequency (usually 33Hz) should be used to ensure the circuitry of the brushless DC motor has enough time to operate. When driving a fan with a PWM-to-DC circuit, as in Figure 6, the highest available frequency (35kHz) should be used to minimize the size of the filter capacitors. When using a fan with a PWM control input, the frequency should normally be high as well, although some fans have PWM inputs that accept low-frequency drive.

The duty cycle of the PWM can be controlled in two ways:

- 1) Manual PWM control by setting the duty cycle of the fan directly through the fan-target duty-cycle register (09h).
- 2) Automatic PWM control by setting the duty cycle based on temperature.

Manual PWM Duty-Cycle Control

Setting bits D5 and D4 to zero in the fan-configuration register (0Dh) enables manual PWMOUT control. In this mode, the duty cycle written to the fan-target dutycycle register controls the PWMOUT duty cycle. The value is clipped to a maximum of 240, which corresponds to a 100% duty cycle. Any value above that is limited to the maximum duty cycle. In manual control mode, the value of the maximum duty-cycle register is ignored and does not affect the duty cycle.

Automatic PWM Duty-Cycle Control

In the automatic control mode, the duty cycle is controlled by the local or remote temperature, according to the settings in the control registers. Below the value of the fan-start temperature threshold (set by registers 03h and 04h), the duty cycle is equal to the fan-start duty cycle. Above the fan-start temperature, the duty cycle increases by one duty-cycle step each time the temperature increases by one temperature step. Below the fanstart temperature, the duty cycle is either 0% or it is equal to the fan-start duty cycle, depending on the value of bit D3 in the configuration byte register. See Figure 8.

The target duty cycle is calculated based on the following formula:

For temperature > fan-start temperature:

$$
DC = FSDC + (T - FST) \times \frac{DCSS}{TS}
$$

where:

DC = DutyCycle

MAXIM

Figure 8. Automatic PWM Duty Control

FSDC = FanStartDutyCycle $T =$ Temperature FST = FanStartTemperature DCSS = DutyCycleStepSize

TS = TempStep

Duty cycle is recalculated after each temperature conversion if temperature is increasing. If the temperature begins to decrease, the duty cycle is not recalculated until the temperature drops by 5°C from the last peak temperature. The duty cycle remains the same until the temperature drops 5°C from the last peak temperature or the temperature rises above the last peak temperature. For example, if temperature goes up to +85°C and starts decreasing, duty cycle is not recalculated until the temperature reaches +80°C or the temperature rises above +85°C. If temperature decreases further, the duty cycle is not updated until it reaches +75°C.

For temperature < fan-start temperature and bit D3 of the configuration byte register $= 0$:

$DutyCycle = 0$

For temperature < fan-start temperature and bit D3 of the configuration byte register $= 1$:

Dutycycle = FanStartDutyCycle

Once the temperature crosses the fan-start temperature threshold, the temperature has to drop below the fan-start temperature threshold minus the hysteresis before the duty cycle returns to either 0% or fan-start duty cycle. The value of the hysteresis is set by D7 of the fan-configuration register.

The duty cycle is limited to the value in the fan maximum duty-cycle register. If the duty-cycle value is larger than the maximum fan duty cycle, it can be set to the maximum fan duty cycle as in the fan maximum dutycycle register. The temp step is bit D6 of the fan-configuration register (0Dh).

If duty cycle is an odd number, the MAX6641 automatically rounds down to the nearest even number.

Duty-Cycle Rate-of-Change Control

To reduce the audibility of changes in fan speed, the rate of change of the duty cycle is limited by the values set in the duty-cycle rate-of-change register. Whenever the target duty cycle is different from the instantaneous duty cycle, the duty cycle increases or decreases at the rate determined by the duty-cycle rate-of-change byte until it reaches the target duty cycle. By setting the rate of change to the appropriate value, the thermal requirements of the system can be balanced against good acoustic performance. Slower rates of change are less noticeable to the user, while faster rates of change can help minimize temperature variations. Remember that the fan controller is part of a complex control system. Because several of the parameters are generally not known, some experimentation may be necessary to arrive at the best settings.

Power-Up Defaults

At power-up, the MAX6641 has the default settings indicated in Table 1. Some of these settings are summarized below:

- Temperature conversions are active.
- Remote \overline{OT} limit = +110°C.
- Local \overline{OT} limit = +80 \degree C.
- Manual fan mode.
- Fan duty cycle $= 0$.
- PWM Invert bit $= 0$.
- PWMOUT is high.

When using an nMOS or npn transistor, the fan starts at full speed on power-up.

Applications Information

Remote-Diode Selection

The MAX6641 can directly measure the die temperature of CPUs and other ICs that have on-board temperature-sensing diodes (see the *Typical Application Circuit*), or they can measure the temperature of a discrete diode-connected transistor.

Pentium is a registered trademark of Intel Corp. Athlon is a trademark of AMD.

14 __

Effect of Ideality Factor

The accuracy of the remote temperature measurements depends on the ideality factor (n) of the remote diode (actually a transistor). The MAX6641 is optimized for $n =$ 1.008, which is the typical value for the Intel Pentium® III and the AMD Athlon™ MP model 6. If a sense transistor with a different ideality factor is used, the output data is different. Fortunately, the difference is predictable.

Assume a remote-diode sensor designed for a nominal ideality factor nNOMINAL is used to measure the temperature of a diode with a different ideality factor, n1. The measured temperature T_M can be corrected using:

$$
T_M = T_{ACTUAL}\left(\frac{n_1}{n_{NOMINAL}}\right)
$$

where temperature is measured in Kelvin.

As mentioned above, the nominal ideality factor of the MAX6641 is 1.008. As an example, assume the MAX6641 is configured with a CPU that has an ideality factor of 1.002. If the diode has no series resistance, the measured data is related to the real temperature as follows:

$$
T_{ACTUAL} = T_M \left(\frac{n_{NOMINAL}}{n_1} \right) = T_M \left(\frac{1.008}{1.002} \right) = T_M (1.00599)
$$

For a real temperature of +85°C (358.15K), the measured temperature is +82.87°C (356.02K), which is an error of -2.13°C.

Effect of Series Resistance

Series resistance in a sense diode contributes additional errors. For nominal diode currents of 10µA and 100µA, change in the measured voltage is:

$$
\Delta V_M = R_S(100\mu A - 10\mu A) = 90\mu A \times R_S
$$

Since 1°C corresponds to 198.6µV, series resistance contributes a temperature offset of:

$$
\frac{90\frac{\mu V}{\Omega}}{198.6\frac{\mu V}{\text{°C}}} = 0.453\frac{\text{°C}}{\Omega}
$$

Assume that the diode being measured has a series resistance of 3Ω. The series resistance contributes an offset of:

$$
3\Omega \times 0.453 \frac{^{\circ}\text{C}}{\Omega} = +1.36^{\circ}\text{C}
$$

MAXIM

The effects of the ideality factor and series resistance are additive. If the diode has an ideality factor of 1.002 and series resistance of 3Ω, the total offset can be calculated by adding error due to series resistance with error due to ideality factor:

 1.36° C - 2.13 $^{\circ}$ C = -0.1477 $^{\circ}$ C

for a diode temperature of +85°C.

In this example, the effect of the series resistance and the ideality factor partially cancel each other.

For best accuracy, the discrete transistor should be a small-signal device with its collector connected to GND and base connected to DXN. Table 6 lists examples of discrete transistors that are appropriate for use with the MAX6641.

The transistor must be a small-signal type with a relatively high forward voltage; otherwise, the A/D input voltage range can be violated. The forward voltage at the highest expected temperature must be greater than 0.25V at 10µA, and at the lowest expected temperature, the forward voltage must be less than 0.95V at 100µA. Large power transistors must not be used. Also, ensure that the base resistance is less than 100 Ω . Tight specifications for forward-current gain (50 < ß <150, for example) indicate that the manufacturer has good process controls and that the devices have consistent VBE characteristics.

ADC Noise Filtering

The integrating ADC used has good noise rejection for low-frequency signals such as 60Hz/120Hz power-supply hum. In noisy environments, high-frequency noise reduction is needed for high-accuracy remote measurements. The noise can be reduced with careful PC board layout and proper external noise filtering.

High-frequency EMI is best filtered at DXP and DXN with an external 2200pF capacitor. Larger capacitor values can be used for added filtering, but do not exceed 3300pF because larger values can introduce errors due to the rise time of the switched current source.

PC Board Layout

Follow these guidelines to reduce the measurement error of the temperature sensors:

1) Place the MAX6641 as close as is practical to the remote diode. In noisy environments, such as a computer motherboard, this distance can be 4in to 8in typically. This length can be increased if the worst noise sources are avoided. Noise sources include CRTs, clock generators, memory buses, and ISA/PCI buses.

Table 6. Remote-Sensor Transistor Manufacturers

- 2) Do not route the DXP-DXN lines next to the deflection coils of a CRT. Also, do not route the traces across fast digital signals, which can easily introduce 30°C error, even with good filtering.
- 3) Route the DXP and DXN traces in parallel and in close proximity to each other, away from any higher voltage traces, such as 12VDC. Leakage currents from PC board contamination must be dealt with carefully since a 20M Ω leakage path from DXP to ground causes about 1°C error. If high-voltage traces are unavoidable, connect guard traces to GND on either side of the DXP-DXN traces (Figure 9).
- 4) Route through as few vias and crossunders as possible to minimize copper/solder thermocouple effects.
- 5) When introducing a thermocouple, make sure that both the DXP and the DXN paths have matching thermocouples. A copper-solder thermocouple exhibits 3µV/°C, and takes about 200µV of voltage error at DXP-DXN to cause a 1°C measurement error. Adding a few thermocouples causes a negligible error.
- 6) Use wide traces. Narrow traces are more inductive and tend to pick up radiated noise. The 10-mil widths and spacing recommended in Figure 9 are not absolutely necessary, as they offer only a minor improvement in leakage and noise over narrow traces. Use wider traces when practical.
- 7) Add a 200 Ω resistor in series with V_{CC} for best noise filtering (see the *Typical Application Circuit*).
- 8) Copper cannot be used as an EMI shield; only ferrous materials such as steel work well. Placing a copper ground plane between the DXP-DXN traces and traces carrying high-frequency noise signals does not help reduce EMI.

MAXIM

Figure 9. Recommended DXP-DXN PC Traces

Twisted-Pair and Shielded Cables

Use a twisted-pair cable to connect the remote sensor for remote-sensor distance longer than 8in or in very noisy environments. Twisted-pair cable lengths can be between 6ft and 12ft before noise introduces excessive errors. For longer distances, the best solution is a shielded twisted pair like that used for audio microphones. For example, Belden 8451 works well for distances up to 100ft in a noisy environment. At the device, connect the twisted pair to DXP and DXN and the shield to GND. Leave the shield unconnected at the remote sensor.

For very long cable runs, the cable's parasitic capacitance often provides noise filtering, so the 2200pF capacitor can often be removed or reduced in value. Cable resistance also affects remote-sensor accuracy. For every 1Ω of series resistance, the error is approximately 0.5 $°C$.

Thermal Mass and Self-Heating

When sensing local temperature, these devices are intended to measure the temperature of the PC board to which they are soldered. The leads provide a good thermal path between the PC board traces and the die. Thermal conductivity between the die and the ambient air is poor by comparison, making air temperature measurements impractical. Because the thermal mass of the PC board is far greater than that of the MAX6641, the devices follow temperature changes on the PC board with little or no perceivable delay. When measuring the temperature of a CPU or other IC with an onchip sense junction, thermal mass has virtually no effect. The measured temperature of the junction tracks the actual temperature within a conversion cycle.

When measuring temperature with discrete remote sensors, smaller packages, such as µMAXes, yield the best thermal response times. Take care to account for thermal gradients between the heat source and the sensor, and ensure stray air currents across the sensor package do not interfere with measurement accuracy. Self-heating does not significantly affect measurement accuracy. Remote-sensor self-heating due to the diode current source is negligible.

SUNSTAR商斯达实业集团是集研发、生产、工程、销售、代理经销 、技术咨询、信息服务等为一体的高 科技企业,是专业高科技电子产品生产厂家,是具有 10 多年历史的专业电子元器件供应商,是中国最早和 最大的仓储式连锁规模经营大型综合电子零部件代理分销商之一,是一家专业代理和分銷世界各大品牌IC 芯片和電子元器件的连锁经营綜合性国际公司。在香港、北京、深圳、上海、西安、成都等全国主要电子 市场设有直属分公司和产品展示展销窗口门市部专卖店及代理分销商,已在全国范围内建成强大统一的供 货和代理分销网络。 我们专业代理经销、开发生产电子元器件、集成电路、传感器、微波光电元器件、工 控机/DOC/DOM电子盘、专用电路、单片机开发、MCU/DSP/ARM/FPGA软件硬件、二极管、三极管、模 块等,是您可靠的一站式现货配套供应商、方案提供商、部件功能模块开发配套商。专业以现代信息产业 (计算机、通讯及传感器)三大支柱之一的传感器为主营业务,专业经营各类传感器的代理、销售生产、 网络信息、科技图书资料及配套产品设计、工程开发。我们的专业网站——[中国传感器科技信息网\(全球](http://www.sensor-ic.com/) [传感器数据库\)](http://www.sensor-ic.com/) **[www.SENSOR-IC.COM](http://www.sensor-ic.com/)** 服务于全球高科技生产商及贸易商,为企业科技产品开发提供技 术交流平台。欢迎各厂商互通有无、交换信息、交换链接、发布寻求代理信息。欢迎国外高科技传感器、 变送器、执行器、自动控制产品厂商介绍产品到 中国,共同开拓市场。本网站是关于各种传感器-变送器-仪器仪表及工业自动化大型专业网站,深入到工业控制、系统工程计 测计量、自动化、安防报警、消费电 子等众多领域,把最新的传感器-变送器-仪器仪表买卖信息,最新技术供求,最新采购商,行业动态,发展方 向,最新的技术应用和市场资讯及时的传递给广大科技开发、科学研究、产品设计人员。本网站已成功为 石油、化工、电力、医药、生物、航空、航天、国防、能源、冶金、电子、工业、农业、交通、汽车、矿 山、煤炭、纺织、信息、通信、IT、安防、环保、印刷、科研、气象、仪器仪表等领域从事科学研究、产 品设计、开发、生产制造的科技人员、管理人员、和采购人员提供满意服务。我公司专业开发生产、代 理、经销、销售各种传感器、变送器、敏感元器件、开关、执行器、仪器仪表、自动化控制系统: 专门从 事设计、生产、销售各种传感器、变送器、各种测控仪表、热工仪表、现场控制器、计算机控制系统、数 据采集系统、各类环境监控系统、专用控制系统应用软件以及嵌入式系统开发及应用等工作。如热敏电阻、 压敏电阻、温度传感器、温度变送器、湿度传感器、 湿度变送器、气体传感器、 气体变送器、压力传感 器、 压力变送、称重传感器、物(液)位传感器、物(液)位变送器、流量传感器、 流量变送器、电流 (压)传感器、溶氧传感器、霍尔传感器 、图像传感器、超声波传感器、位移传感器、速度传感器、加速 度传感器、扭距传感器、红外传感器、紫外传感器、 火焰传感器、激光传感器、振动传感器、轴角传感器、 光电传感器、接近传感器、干簧管传感器、继电器传感器、微型电泵、磁敏(阻)传感器 、压力开关、接 近开关、光电开关、色标传感器、光纤传感器、齿轮测速传感器、 时间继电器、计数器、计米器、温控仪、 固态继电器、调压模块、电磁铁、电压表、电流表等特殊传感器 。 同时承接传感器应用电路、产品设计 和自动化工程项目。
