FEATURES

Small and thin

4 mm \times 4 mm \times 1.45 mm LFCSP package

3 mg resolution at 50 Hz

Wide supply voltage range: 2.4 V to 6 V

Low power: 350 μA at $V_S = 2.4\text{ V}$ (typ)

Good zero g bias stability

Good sensitivity accuracy

X-axis and Y-axis aligned to within 0.1° (typ)

BW adjustment with a single capacitor

Single-supply operation

10,000 g shock survival

Compatible with Sn/Pb and Pb-free solder processes

APPLICATIONS

Vibration monitoring and compensation

Abuse event detection

Sports equipment

GENERAL DESCRIPTION

The ADXL321 is a small and thin, low power, complete dual-axis accelerometer with signal conditioned voltage outputs, which is all on a single monolithic IC. The product measures acceleration with a full-scale range of $\pm 18\text{ g}$ (typical). It can also measure both dynamic acceleration (vibration) and static acceleration (gravity).

The ADXL321's typical noise floor is $320\text{ }\mu\text{g}/\sqrt{\text{Hz}}$, allowing signals below 3 mg to be resolved in tilt-sensing applications using narrow bandwidths ($< 50\text{ Hz}$).

The user selects the bandwidth of the accelerometer using capacitors C_X and C_Y at the X_{OUT} and Y_{OUT} pins. Bandwidths of 0.5 Hz to 2.5 kHz may be selected to suit the application.

The ADXL321 is available in a very thin 4 mm \times 4 mm \times 1.45 mm, 16-lead, plastic LFCSP.

Turn-On Time ⁷			20		ms
TEMPERATURE					
Operating Temperature Range		-20		+70	$^\circ\text{C}$

¹ All minimum and maximum specifications are guaranteed. Typical specifications are not guaranteed.

² Sensitivity is essentially ratiometric to V_S .

³ Defined as the change from ambient-to-maximum temperature or ambient-to-minimum temperature.

⁴ Actual frequency response controlled by user-supplied external capacitor (C_X , C_Y).

⁵ Bandwidth = $1/(2 \times \pi \times 32\text{ k}\Omega \times C)$. For C_X , $C_Y = 0.002\ \mu\text{F}$, bandwidth = 2500 Hz. For C_X , $C_Y = 10\ \mu\text{F}$, bandwidth = 0.5 Hz. Minimum/maximum values are not tested.

⁶ Self-test response changes cubically with V_S .

⁷ Larger values of C_X , C_Y increase turn-on time. Turn-on time is approximately $160 \times C_X$ or $C_Y + 4\text{ ms}$, where C_X , C_Y are in μF .

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Acceleration (Any Axis, Unpowered)	10,000 <i>g</i>
Acceleration (Any Axis, Powered)	10,000 <i>g</i>
V _s	-0.3 V to +7.0 V
All Other Pins	(COM - 0.3 V) to (V _s + 0.3 V)
Output Short-Circuit Duration (Any Pin to Common)	Indefinite
Operating Temperature Range	-55°C to +125°C
Storage Temperature	-65°C to +150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The ADXL321 is a complete acceleration measurement system on a single monolithic IC. The ADXL321 has a measurement range of $\pm 18 g$. It contains a polysilicon surface-micromachined sensor and signal conditioning circuitry to implement an open-loop acceleration measurement architecture. The output signals are analog voltages that are proportional to acceleration. The accelerometer measures static acceleration forces, such as gravity, which allows it to be used as a tilt sensor.

The sensor is a polysilicon surface-micromachined structure built on top of a silicon wafer. Polysilicon springs suspend the structure over the surface of the wafer and provide a resistance against acceleration forces. Deflection of the structure is measured using a differential capacitor that consists of independent fixed plates and plates attached to the moving mass. The fixed plates are driven by 180° out-of-phase square waves. Acceleration deflects the beam and unbalances the differential capacitor, resulting in an output square wave whose amplitude is proportional to acceleration. Phase-sensitive demodulation techniques are then used to rectify the signal and determine the direction of the acceleration.

The demodulator's output is amplified and brought off-chip through a $32 k\Omega$ resistor. The user then sets the signal bandwidth of the device by adding a capacitor. This filtering improves measurement resolution and helps prevent aliasing.

PERFORMANCE

Rather than using additional temperature compensation circuitry, innovative design techniques have been used to ensure high performance is built-in. As a result, there is neither quantization error nor nonmonotonic behavior, and temperature hysteresis is very low (typically less than $10 mg$ over the $-20^\circ C$ to $+70^\circ C$ temperature range).

Figure 10 shows the zero g output performance of eight parts (X- and Y-axis) over a $-20^\circ C$ to $+70^\circ C$ temperature range.

Figure 13 demonstrates the typical sensitivity shift over temperature for supply voltages of $3 V$. This is typically better than $\pm 1\%$ over the $-20^\circ C$ to $+70^\circ C$ temperature range.

APPLICATIONS

POWER SUPPLY DECOUPLING

For most applications, a single 0.1 μF capacitor, C_{DC} , adequately decouples the accelerometer from noise on the power supply. However, in some cases, particularly where noise is present at the 140 kHz internal clock frequency (or any harmonic thereof), noise on the supply may cause interference on the ADXL321 output. If additional decoupling is needed, a 100 Ω (or smaller) resistor or ferrite bead may be inserted in the supply line. Additionally, a larger bulk bypass capacitor (in the 1 μF to 4.7 μF range) may be added in parallel to C_{DC} .

SETTING THE BANDWIDTH USING C_X AND C_Y

The ADXL321 has provisions for band-limiting the X_{OUT} and Y_{OUT} pins. Capacitors must be added at these pins to implement low-pass filtering for antialiasing and noise reduction. The equation for the 3 dB bandwidth is

$$F_{-3\text{dB}} = 1/(2\pi(32\text{ k}\Omega) \times C_{(X,Y)})$$

or more simply,

$$F_{-3\text{dB}} = 5\ \mu\text{F}/C_{(X,Y)}$$

The tolerance of the internal resistor (R_{FILT}) typically varies as much as $\pm 15\%$ of its nominal value (32 k Ω), and the bandwidth varies accordingly. A minimum capacitance of 2000 pF for C_X and C_Y is required in all cases.

Table 5. Filter Capacitor Selection, C_X and C_Y

Bandwidth (Hz)	Capacitor (μF)
1	4.7
10	0.47
50	0.10
100	0.05
200	0.027
500	0.01

SELF-TEST

The ST pin controls the self-test feature. When this pin is set to V_S , an electrostatic force is exerted on the accelerometer beam. The resulting movement of the beam allows the user to test if the accelerometer is functional. The typical change in output is 315 mg (corresponding to 18 mV). This pin may be left open-circuit or connected to common (COM) in normal use.

The ST pin should never be exposed to voltages greater than $V_S + 0.3\text{ V}$. If this cannot be guaranteed due to the system design (for instance, if there are multiple supply voltages), then a low V_F clamping diode between ST and V_S is recommended.

DESIGN TRADE-OFFS FOR SELECTING FILTER CHARACTERISTICS: THE NOISE/BW TRADE-OFF

The accelerometer bandwidth selected ultimately determines the measurement resolution (smallest detectable acceleration). Filtering can be used to lower the noise floor, which improves the resolution of the accelerometer. Resolution is dependent on the analog filter bandwidth at X_{OUT} and Y_{OUT} .

The output of the ADXL321 has a typical bandwidth of 2.5 kHz. The user must filter the signal at this point to limit aliasing errors. The analog bandwidth must be no more than half the A/D sampling frequency to minimize aliasing. The analog bandwidth may be further decreased to reduce noise and improve resolution.

The ADXL321 noise has the characteristics of white Gaussian noise, which contributes equally at all frequencies and is described in terms of $\mu\text{g}/\sqrt{\text{Hz}}$ (the noise is proportional to the square root of the accelerometer's bandwidth). The user should limit bandwidth to the lowest frequency needed by the application in order to maximize the resolution and dynamic range of the accelerometer.

With the single-pole, roll-off characteristic, the typical noise of the ADXL321 is determined by

$$rmsNoise = (320\ \mu\text{g}/\sqrt{\text{Hz}}) \times (\sqrt{\text{BW} \times 1.6})$$

At 100 Hz bandwidth the noise will be

$$rmsNoise = (320\ \mu\text{g}/\sqrt{\text{Hz}}) \times (\sqrt{100 \times 1.6}) = 4\text{ mg}$$

Often, the peak value of the noise is desired. Peak-to-peak noise can only be estimated by statistical methods. A factor of 6 is generally used to convert rms to peak-to-peak. Table 6 is useful for estimating the probabilities of exceeding various peak values, given the rms value.

Table 6. Estimation of Peak-to-Peak Noise

Peak-to-Peak Value	% of Time That Noise Exceeds Nominal Peak-to-Peak Value
$2 \times rms$	32
$4 \times rms$	4.6
$6 \times rms$	0.27
$8 \times rms$	0.006

Peak-to-peak noise values give the best estimate of the uncertainty in a single measurement. Table 7 gives the typical noise output of the ADXL321 for various C_X and C_Y values.

Table 7. Filter Capacitor Selection (C_X , C_Y)

Bandwidth (Hz)	C_X , C_Y (μF)	RMS Noise (mg)	Peak-to-Peak Noise Estimate (mg)
10	0.47	1.3	7.8
50	0.1	2.9	17.4
100	0.047	4	24
500	0.01	9.1	54.6

USE WITH OPERATING VOLTAGES OTHER THAN 3 V

The ADXL321 is tested and specified at $V_S = 3 V$; however, it can be powered with V_S as low as 2.4 V or as high as 6 V. Note that some performance parameters change as the supply voltage is varied.

The ADXL321 output is ratiometric, so the sensitivity (or scale factor) varies proportionally to supply voltage. At $V_S = 5 V$, the sensitivity is typically 100 mV/g. At $V_S = 2.4 V$, the sensitivity is typically 45 mV/g.

The zero g bias output is also ratiometric, so the zero g output is nominally equal to $V_S/2$ at all supply voltages.

The output noise is not ratiometric but is absolute in volts; therefore, the noise density decreases as the supply voltage increases. This is because the scale factor (mV/g) increases while the noise voltage remains constant. At $V_S = 5 V$, the noise density is typically $190 \mu g/\sqrt{Hz}$, while at $V_S = 2.4 V$, the noise density is typically $400 \mu g/\sqrt{Hz}$.

Self-test response in g is roughly proportional to the square of the supply voltage. However, when ratiometricity of sensitivity is factored in with supply voltage, the self-test response in volts is roughly proportional to the cube of the supply voltage. For example, at $V_S = 5 V$, the self-test response for the ADXL321 is approximately 80 mV. At $V_S = 2.4 V$, the self-test response is approximately 8 mV.

The supply current decreases as the supply voltage decreases. Typical current consumption at $V_S = 5 V$ is 750 μA , and typical current consumption at $V_S = 2.4 V$ is 350 μA .

USE AS A DUAL-AXIS TILT SENSOR

An accelerometer is most sensitive to tilt when its sensitive axis is perpendicular to the force of gravity (that is, when it is parallel to the earth's surface). At this orientation, its sensitivity to changes in tilt is highest. When the accelerometer is oriented on axis to gravity (near its +1 g or -1 g reading), the change in output acceleration per degree of tilt is negligible. When the accelerometer is perpendicular to gravity, its output changes nearly 17.5 mg per degree of tilt. At 45°, its output changes at only 12.2 mg per degree of tilt, and resolution declines.

Converting Acceleration to Tilt

When the accelerometer is oriented so both its X-axis and Y-axis are parallel to the earth's surface, it can be used as a 2-axis tilt sensor with both a roll axis and pitch axis. Once the output signal from the accelerometer has been converted to an acceleration that varies between -1 g and +1 g, the output tilt in degrees is calculated as

$$PITCH = \arcsine(A_X/1 g)$$

$$ROLL = \arcsine(A_Y/1 g)$$

Be sure to account for overranges. It is possible for the accelerometers to output a signal greater than $\pm 1 g$ due to vibration, shock, or other accelerations.
