# Sensors

Mechanical Sensors
Powder Level Sensors

TS-L, -M, -H Series

Plain paper copiers and laser printers require the toner (pigment powder) and carrier (magnetic powder) to be mixed in the proper proportions to create the developer. TDK's TS series of toner sensors was designed to maintain this correct mix ratio.

FEATURES

- The TS-L, TS-M and TS-H toner sensors use a high performance ferrite core differential transformer with an adjustable control lead wires. When the DC voltage applied to the control lead wires is varied, the sensor working point also varies. Since the control lead wires (and working point) can be set to practically any desired value, it provides the following capabilities:
- The sensor adjustment point can be installed at any location most convenient for operation.
- Because it has such a wide control range, the working point can be reset easily after changing the developer, or whenever needed.
- The microprocessor in the printer or copier can vary the control lead voltage for automatic adjustment.
- In multi-color printers, it is no longer necessary to use a different constant sensor for each color. One TDK programmable toner sensor can accommodate the working point differences of each color toner with easily adjustable control voltage.
- The compact size of the sensors makes them easy to install in virtually any locations.

PRODUCT IDENTIFICATION

  10:DC.10V(Standard)

(3) Power supply voltage*2
  24:DC.24V(Standard)

(4) Sensor construction*3
  L: TH core(Standard)
  M: TH+RI core(Shielded)
  H: R+RI core(High efficiency magnetic circuit)

(5) Sensor protrusion length*4
  B: 4.5mm (Standard)
  A: 3mm
  C: 7.5mm

(6) TDK internal code*5

*1, *2 Please contact TDK for applications requiring non-standard voltages.

*3 M or H model should be used for applications particularly requiring avoidance of effects caused by the sensor lateral surfaces. Usage conditions should be considered carefully when selecting model H, which is designed for high sensitivity. Due to low cost, model L is also used as an out-of-toner sensor.

*4 The most appropriate sensor protrusion length should be selected during design of the toner/carrier tank.

*5 Two character control code using by TDK during sampling.

- Standard ratings include the sensor sensitivity and the output filter time constant.

## Mechanical Sensors
Powder Level Sensors

TS-L, -M, -H Series

PRECAUTIONS

Adhere to the following recommendations to ensure stable operation of the programmable toner sensor.

Values shown here are guidelines for general design. Detection sensitivity of sensors is influenced by the material and shape of the developer container that the sensor will be used with, and the mechanism for carrying the developer. Refer to separate documents for special design specifications.

1. The quantity of developer (toner carrier) around the sensor face

The detection sensitivity will drop when the quantity of developer around the sensor face (D in the diagram below) is low (below 5mm). Increasing the sensitivity of the sensor itself through the circuiting can compensate for this. However, as sensor sensitivity increases, environmental and temperature resistance characteristics deteriorate, causing decresed stability of operation. Design the developer container and the mechanism for carrying the developer so that there is a minimum of 6mm (D in the diagram below).

2. Influence of an external magnetic field near the sensor

If a DC magnetic field is applied near the sensor, the sensors working point will need to be changed correspondingly.
If the DC magnetic field strength changes depending on the individual device, the working point of the sensor will need to be reset depending on the DC magnetic field. The best environment is one where there is no DC magnetic field. however if this is unavoidable, it is recommended that you either apply a magnetic shield at the source of the DC magnetic field, or use the TS-M series that has a magnetic shield core for the sensor.

If the DC magnetic field is strong, it may be necessary to use the TS-M series possessing a magnetic shield core, or the highly sensitive TS-H series with a large core for the sensor coil. As shown in the diagram above, however, the carrier that is in the developer

may become trapped over the core, impairing the performance of the sensor. (The TS-L series uses a small core so this situation rarely occurs.)

3. Influence of conductive material near the sensor

A conductive material placed near the sensor can also change its working point. If a certain distance is kept between them, normal operation can be recovered by resetting the working point. However, if the conductor is quite close to the sensor, as in the diagram below, the adjustment range for the working point may be exceeded.

A: Conductors such as aluminum plates

If the sensor is installed on a conductor such as aluminum, it may not function at all since the driving power of the sensor coil will be shorted. This phenomenon is most pronounced with the TS-L series. The TS-M and TS-H series can be installed on conductive surfaces, but the working point adjustment will vary widely from installation to installation due to the close relationship between the mounting and the fluctuation margin of the working point. This complicates adjustment procedures.
A: Conductors such as aluminum plates

If the application requires installing a sensor on aluminum, working point changes can be reduced first by placing a plastic plate of at least ø30mm in diameter over the aluminum. Even with this method, some variability in working point can be expected.

A: Conductors such as aluminum plates
B: Non-conductive material such as plastic

4. Causes of ripple of detection output

Ripple in the output detection occurs when the flow rate of developer around the sensor is unstable. Depending on the size of the ripple, this can considerably lower control accuracy. For this reason it is best to locate the sensor where the flow of developer is smooth. The sensor itself contains a built-in filter for absorbing ripples, so there are generally no problems with a normal level of ripple. However if the size of the ripples exceed ordinary levels, difficulties such as those describe below may occur.

⚠TDK

Sensors

Mechanical Sensors
Powder Level Sensors

TS-L, -M, -H Series
The above illustration is a model of how unstable developer flow leads to ripple in the detection output. If there is a comparatively small fluctuation in developer flow ($C_0 \rightarrow C_1 \rightarrow C_0 \rightarrow C_2 \rightarrow C_0$) around the working point C_0, this will be reflected in an output ripple between E_1 and E_2. As long as the fluctuation in the output ripple remains within the developer working range, the output signal filtering is sufficient to ensure stable sensor characteristics. However, if the flow of developer fluctuates in a more unstable pattern, such as $C_0 \rightarrow C_3 \rightarrow C_0 \rightarrow C_4 \rightarrow C_0$, the sensor saturation range may be exceeded as shown by the output ripple peaks E_3 and E_4. In this case sensing only takes place from P_0 to P_1, P_2 to P_3, and P_5 to P_6. Sensing does not take place between P_1 to P_2, or P_4 to P_5 due to saturation. Sensitivity is greatly reduced because of this.

It is possible of course to reduce the ripples through filtering. However, saturation reduces the sensitivity of the sensor itself. In order to maintain the same high level of sensitivity as when there are only small ripples below saturation levels after filtering, the sensitivity needs to be increased in advance. Unfortunately, increasing the sensitivity (increasing the sensitivity to changes in the flow of developer), leads to a larger output ripple. Not only this, but as the S/N ratio does not change when sensitivity is increased, there is no increase in control accuracy, and sensor environmental characteristics are impaired as well, resulting in even more unstable sensing.
The following is another reason for avoiding large ripples.

The previous diagram shows an extremely unstable case where the developer flow fluctuates between C_1 and C_2. In this model, two sensors, A and B are installed. Apart from having different saturation points they are identical sensors. "a" is the saturation point for sensor A, and "b" is the saturation point of sensor B. With flow fluctuating as shown ($C_0 \rightarrow C_1 \rightarrow C_0 \rightarrow C_2 \rightarrow C_0$), there will be two out-

put ripples, $E_1(a)$ to E_2, and $E_1(b)$ to E_2. After filtering, the average output EA and EB are of course different.

What this model shows is that two sensors with the same characteristics in the working range before reaching saturation, have different outputs when there is a large ripple, causing further problems with the sensitivity of the sensors. With a large ripple, sensitivity must be adjusted individually in order to keep the output level and sensitivity of each sensor the same. This is obviously an extremely difficult task.

These problems indicate that the problem of output ripples is not just a problem of filter characteristics, and the importance of the stable operation of each installation is emphasized. As TDK programmable toner filters are equipped with a built in filter, any ripples that appear in sensor output are what is left after filtering. When designing the developer container it is best to temporarily remove the sensor filter so that you can view the ripples directly influenced by developer instability.

5. Relation between sensor sensitivity and sensor output voltage.

TDK programmable toner sensors are set with an output center value of 2.5V for the purposes of compatibility with other applications. When the output center values of 2.5V and 5V are compared however, the 5V type has around two times the output voltage fluctuation of the 2.5V type, for the same toner density fluctuation. This shows that the 5V version has around half the sensitivity of the 2.5V version, at the same V/wt%. So the 5V type has far better environment resistance characteristics than the 2.5V type. In view of these things, the 5V type is recommended when designing a new installation.
