Notes

- The quoted values of ΔV_{ref} are based on a constant current I_Z . Two factors can cause ΔV_{ref} to change, namely the differential resistance r_{dif} and the temperature coefficient S_Z .
 - As the max. r_{dif} of the device can be 50 Ω , a change of 0.01 mA in the current through the reference diode will result in a ΔV_{ref} of 0.01 mA \times 50 Ω = 0.5 mV. This level of ΔV_{ref} is not significant on a BZV10 ($\Delta V_{ref} < 46\text{ mV}$), it is however very significant on a BZV14 ($\Delta V_{ref} < 2.3\text{ mV}$).
 - The temperature coefficient of the reference voltage S_Z is a function of I_Z . Reference diodes are classified at the specified test current, and the S_Z of the reference diode will be different at different levels of I_Z . The absolute value of I_Z is important, however, the stability of I_Z , once the level has been set, is far more significant. This applies particularly to the BZV13 and BZV14. The effect of the stability of I_Z on S_Z is shown in Fig.2.
- All reference diodes are characterized by the 'box method'. This guarantees a maximum voltage excursion (ΔV_{ref}) over the specified temperature range, at the specified test current (I_Z), verified by tests at indicated temperature points within the range. V_Z is measured and recorded at each temperature specified. The ΔV_{ref} between the highest and lowest values must not exceed the maximum ΔV_{ref} given. Therefore the temperature coefficient is only given as

a reference. It may be derived from:
$$S_Z = \frac{V_{ref1} - V_{ref2}}{T_{amb2} - T_{amb1}} \times \frac{100}{V_{ref\ nom}} \text{ %/K}$$
