Notes:
1. $t_{HZ}$, $t_{OHZ}$ and $t_{WHZ}$ are defined as the time at which the outputs achieve the open circuit conditions and are not referred to output voltage levels.
2. This parameter is sampled and not 100% tested.
3. A write occurs during the overlap ($t_{WP}$) of a low CS# and a low WE#. A write begins at the later transition of CS# going low or WE# going low. A write ends at the earlier transition of CS# going high or WE# going high. $t_{WP}$ is measured from the beginning of write to the end of write.
4. $t_{CW}$ is measured from CS# going low to the end of write.
5. $t_{AS}$ is measured from the address valid to the beginning of write.
6. $t_{WR}$ is measured from the earlier of WE# or CS# going high to the end of write cycle.
7. During this period, I/O pins are in the output state so that the input signals of the opposite phase to the outputs must not be applied.
8. If the CS# low transition occurs simultaneously with the WE# low transition or after the WE# transition, the output remain in a high impedance state.
9. Dout is the same phase of the write data of this write cycle.
10. Dout is the read data of next address.
11. If CS# is low during this period, I/O pins are in the output state. Therefore, the input signals of the opposite phase to the outputs must not be applied to them.
12. In the write cycle with OE# low fixed, $t_{WP}$ must satisfy the following equation to avoid a problem of data bus contention. $t_{WP} \geq t_{DW}$ min + $t_{WHZ}$ max

| Operation recovery time | | $t_R$ | $t_{RC}$*5 | — | — | ns | |

Notes: 1. This characteristic is guaranteed only for L version.
2. This characteristic is guaranteed only for SL version.
3. CS# controls address buffer, WE# buffer, OE# buffer, and Din buffer. In data retention mode, Vin levels (address, WE#, OE#, I/O) can be in the high impedance state.
4. Typical values are at $V_{CC}$ = 3.0 V, Ta = +25°C and specified loading, and not guaranteed.
5. $t_{RC}$ = read cycle time.
